Presentation Overview

Background on regulatory environment

Goals of the present study

Findings

Findings from other sources

Conclusions

Background

Current Santa Ana Basin Plan bacteria objectives based on 1948-1950 studies

Total and fecal coliform regulated

These early studies were flawed

1986 EPA recommended using *E. coli* or Enterococci standards for fresh waters

Based on acceptable risk level and statistical distribution, not single sample max

Study Goals

Determine trends, if any, in bacteriological data

Does weather make a difference?

Wet weather versus dry weather

Does level of development in the watershed make a difference?

Developed versus undeveloped

Does season make a difference?

Winter versus summer

Are there any long term trends?

∴ Cutoff Levels used for this Study

Total Coliform (beach posting level)

Single Sample: 10,000 MPN/100mL

Geometric Mean: 1,000 MPN/100mL

Fecal Coliform (existing water quality standards and beach posting level)

Single Sample: 400 MPN/100mL

Geometric Mean: 200 MPN/100mL

Enterococci (EPA recommended criteria)

Single Sample: 247 MPN/100mL

Geometric Mean: 54 MPN/100mL

Values based on 1.0% risk, 95th percentile

Wet weather = 0.1" or more of rain within two days of sample date

Data Used in this Study

Collected by Orange County Health Care Agency

Data available for period of:

Enterococci: 1999-2004

Fecal Coliform: 1986-2004

Total Coliform: 1986-2004

Samples collected once per week at all sites, rain or shine

Other Studies and Findings

Los Angeles County, 2001

Vacant land has significantly less bacteria in runoff than other land uses, though all land use types exceed applicable criteria

Vacant land in study was inland, steep watershed near Monrovia

Moore, 2001

Storm drains can be major sources of dry-weather bacteria

LA RWQCB, 2004

Birds, beach itself may be sources of bacteria

GeoSyntec, 2005

Bacteria re-growth occurs rapidly downstream of BMPs

Colford et al, 2005

Mission Bay swimming illnesses not correlated with levels of indicator bacteria

Conclusions

Wet-weather samples generally have greater bacteria concentrations than dry-weather samples

Level of Development not a factor for OC coastal creeks

No clear long-term trends

Appear to be many sources, including natural, of bacteria

Rapid regrowth occurs in the environment

Nearly all watersheds exceed current and EPA recommended criteria

Icehouse Canyon Creek (and perhaps other mountain watersheds) may have lower concentrations than OC coastal watersheds
